Upgrade

NI-AI System Security Plan (SSP)

2. System Overview

Purpose

NI-AI (Natural Intellect Artificial Intelligence) is a governance-oriented cognitive support framework designed to provide controlled, auditable, and authority-aligned human-AI interaction.

The system is architected to maintain contextual continuity, identity assurance, operational stability, and authorization integrity across supported environments.

Unlike autonomous decision-making systems, NI-AI functions as an interpretation and coordination layer. Final authority remains with approved human stakeholders and established governance policies.

Architectural Principles

NI-AI is built upon four foundational functions:

Meaning

Interpretation of user input and contextual information.

Context preservation across interactions.

Traceable reasoning support.

Judgment

Governance validation and policy enforcement.

Risk evaluation and escalation management.

Authority verification before execution.

Order

Controlled execution of approved actions.

Sequential processing safeguards.

Operational consistency controls.

Identity

Authentication, authorization, and accountability.

Verification of user authority and permissions.

Audit-ready access control mechanisms.

Core Components

The NI-AI platform consists of:

NI-AI Interpretation Layer

EchoAuth Identity and Authorization Framework

Meaning Coordination Governance (MCG)

Controlled Execution Governor (CEG)

Stability Regulation Services

Audit and Traceability Services
Context Preservation Engine
Monitoring and Integrity Services

Deployment Model

NI-AI may operate within:

Government Cloud Environments
Hybrid Cloud Architectures
On-Premises Secure Facilities
Edge Computing Deployments

Deployment configurations are subject to organizational security requirements and applicable regulatory controls.

Security Philosophy

NI-AI is designed around a refusal-first governance model.

When authority, context, identity, or policy requirements cannot be verified, the system defaults to a restricted or non-executing state until validation requirements are satisfied.

This approach supports:

Least privilege principles
Human oversight requirements
Auditability

Deterministic authorization

Operational safety

Intended Use Cases

NI-AI is intended to support environments requiring:

Identity assurance

Governance-controlled workflows

Context-aware decision support

Human-supervised AI interaction

Traceable authorization processes

Secure multi-party coordination

The system is not intended to operate as an autonomous decision-maker and does not replace human authority, organizational governance, or regulatory oversight.
